Guiding Land Conservation for Biodiversity in Massachusetts

Introduction

In this report, the Natural Heritage & Endangered Species Program provides you with site-specific biodiversity information for your area. Protecting our biodiversity today will help ensure the full variety of species and natural communities that comprise our native flora and fauna will persist for generatons to come.

The information in this report is the result of two statewide biodiversity conservation planning projects, BioMap and Living Waters. The goal of the BioMap project, completed in 2001, was to identify and delineate the most important areas for the long-term viability of terrestrial, wetland, and estuarine elements of biodiversity in Massachusetts. The goal of the Living Waters project, completed in 2003, was to identify and delineate the rivers, streams, lakes, and ponds that are important for freshwater biodiversity in the Commonwealth. These two conservation plans are based on documented observations of rare species, natural communities, and exemplary habitats.

What is a Core Habitat?

Both BioMap and Living Waters delineate Core *Habitats* that identify the most critical sites for biodiversity conservation across the state. Core Habitats represent habitat for the state's most viable rare plant and animal populations and include exemplary natural communities and aquatic habitats. Core Habitats represent a wide diversity of rare species and natural communities (see Table 1), and these areas are also thought to contain virtually all of the other described species in Massachusetts. Statewide, BioMap Core Habitats encompass 1,380,000 acres of uplands and wetlands, and Living Waters identifies 429 Core Habitats in rivers, streams, lakes, and ponds.

Get your copy of the BioMap and Living Waters reports! Contact Natural Heritage at 508-792-7270, Ext. 200 or email natural.heritage@state.ma.us. Posters and detailed technical reports are also available.

Core Habitats and Land Conservation

One of the most effective ways to protect biodiversity for future generations is to protect Core Habitats from adverse human impacts through land conservation. For Living Waters Core Habitats, protection efforts should focus on the *riparian areas*, the areas of land adjacent to water bodies. A naturally vegetated buffer that extends 330 feet (100 meters) from the water's edge helps to maintain cooler water temperature and to maintain the nutrients, energy, and natural flow of water needed by freshwater species.

In Support of Core Habitats

To further ensure the protection of Core Habitats and Massachusetts' biodiversity in the long-term, the BioMap and Living Waters projects identify two additional areas that help support Core Habitats.

In BioMap, areas shown as Supporting Natural *Landscape* provide buffers around the Core Habitats, connectivity between Core Habitats, sufficient space for ecosystems to function, and contiguous undeveloped habitat for common species. Supporting Natural Landscape was

Massachusetts Division of Fisheries and Wildlife

BioMap and Living Waters:

Guiding Land Conservation for Biodiversity in Massachusetts

D:- M---

generated using a Geographic Information Systems (GIS) model, and its exact boundaries are less important than the general areas that it identifies. Supporting Natural Landscape represents potential land protection priorities once Core Habitat protection has been addressed.

In Living Waters, *Critical Supporting Watersheds* highlight the immediate portion of the watershed that sustains, or possibly degrades, each freshwater Core Habitat. These areas were also identified using a GIS model. Critical Supporting Watersheds represent developed and undeveloped lands, and can be quite large. Critical Supporting Watersheds can be helpful in land-use planning, and while they are not shown on these maps, they can be viewed in the Living Waters report or downloaded from www.mass.gov/mgis.

Understanding Core Habitat Species, Community, and Habitat Lists

What's in the List?

Included in this report is a list of the species, natural communities, and/or aquatic habitats for each Core Habitat in your city or town. The lists are organized by Core Habitat number.

For the larger Core Habitats that span more than one town, the species and community lists refer to the <u>entire</u> Core Habitat, not just the portion that falls within your city or town. For a list of <u>all</u> the state-listed rare species within your city or town's boundary, whether or not they are in Core Habitat, please see the town rare species lists available at <u>www.nhesp.org</u>.

The list of species and communities within a Core Habitat contains <u>only</u> the species and

Table 1. The number of rare species and types of natural communities explicitly included in the BioMap and Living Waters conservation plans, relative to the total number of native species statewide.

Mussels	7	12	
Aquatic Invertebrates	23	An estimated > 2500	

natural communities that were explicitly included in a given BioMap or Living Waters Core Habitat. Other rare species or examples of other natural communities may fall within the Core Habitat, but for various reasons are not included in the list. For instance, there are a few rare species that are omitted from the list or summary because of their particular sensitivity to the threat of collection. Likewise, the content of many very small Core Habitats are not described in this report or list, often because they contain a single location of a rare plant

Massachusetts Division of Fisheries and Wildlife

BioMap and Living Waters:

Guiding Land Conservation for Biodiversity in Massachusetts

species. Some Core Habitats were created for suites of common species, such as forest birds, which are particularly threatened by habitat fragmentation. In these cases, the individual common species are not listed.

What does 'Status' mean?

The Division of Fisheries and Wildlife determines a status category for each rare species listed under the Massachusetts Endangered Species Act, M.G.L. c.131A, and its implementing regulations, 321 CMR 10.00. Rare species are categorized as Endangered, Threatened, or of Special Concern according to the following:

- Endangered species are in danger of extinction throughout all or a significant portion of their range or are in danger of extirpation from Massachusetts.
- *Threatened* species are likely to become Endangered in Massachusetts in the foreseeable future throughout all or a significant portion of their range.
- **Special Concern** species have suffered a decline that could threaten the species if allowed to continue unchecked or occur in such small numbers or with such restricted distribution or specialized habitat requirements that they could easily become Threatened in Massachusetts.

In addition, the Natural Heritage & Endangered Species Program maintains an unofficial watch list of plants that are tracked due to potential conservation interest or concern, but are not regulated under the Massachusetts Endangered Species Act or other laws or regulations. Likewise, described natural communities are not regulated any laws or regulations, but they can help to identify ecologically important areas that are worthy of protection. The status of natural

Legal Protection of Biodiversity

BioMap and Living Waters present a powerful vision of what Massachusetts would look like with full protection of the land that supports most of our biodiversity. To create this vision, some populations of state-listed rare species were deemed more likely to survive over the long-term than others.

Regardless of their potential viability, all sites of state-listed species have full legal protection under the Massachusetts Endangered Species Act (M.G.L. c.131A) and its implementing regulations (321 CMR 10.00). Habitat of state-listed wildlife is also protected under the Wetlands Protection Act Regulations (310 CMR 10.37 and 10.59). The *Massachusetts Natural Heritage Atlas* shows Priority Habitats, which are used for regulation under the Massachusetts Endangered Species Act and Massachusetts Environmental Policy Act (M.G.L. c.30) and Estimated Habitats, which are used for regulation of rare wildlife habitat under the Wetlands Protection Act. For more information on rare species regulations, see the *Massachusetts Natural Heritage Atlas*, available from the Natural Heritage & Endangered Species Program in book and CD formats.

BioMap and Living Waters are conservation planning tools and do not, in any way, supplant the Estimated and Priority Habitat Maps which have regulatory significance. Unless and until the combined BioMap and Living Waters vision is fully realized, we must continue to protect all populations of our state-listed species and their habitats through environmental regulation.

communities reflects the documented number and acreages of each community type in the state:

- Critically Imperiled communities typically have 5 or fewer documented sites or have very few remaining acres in the state.
- *Imperiled* communities typically have 6-20 sites or few remaining acres in the state.
- *Vulnerable* communities typically have 21-100 sites or limited acreage across the state.
- **Secure** communities typically have over 100 sites or abundant acreage across the state; however excellent examples are identified as Core Habitat to ensure continued protection.

Massachusetts Division of Fisheries and Wildlife

Understanding Core Habitat Summaries

Following the BioMap and Living Waters Core Habitat species and community lists, there is a descriptive summary of each Core Habitat that occurs in your city or town. This summary highlights some of the outstanding characteristics of each Core Habitat, and will help you learn more about your city or town's biodiversity. You can find out more information about many of these species and natural communities by looking at specific *fact sheets* at www.nhesp.org.

Next Steps

BioMap and Living Waters were created in part to help cities and towns prioritize their land protection efforts. While there are many reasons to conserve land – drinking water protection, recreation, agriculture, aesthetics, and others – BioMap and Living Waters Core Habitats are especially helpful to municipalities seeking to protect the rare species, natural communities, and overall biodiversity within their boundaries. Please use this report and map along with the rare species and community fact sheets to appreciate and understand the biological treasures in your city or town.

Protecting Larger Core Habitats

Core Habitats vary considerably in size. For example, the average BioMap Core Habitat is 800 acres, but Core Habitats can range from less than 10 acres to greater than 100,000 acres. These larger areas reflect the amount of land needed by some animal species for breeding, feeding, nesting, overwintering, and long-term survival. Protecting areas of this size can be

very challenging, and requires developing partnerships with neighboring towns.

Prioritizing the protection of certain areas within larger Core Habitats can be accomplished through further consultation with Natural Heritage Program biologists, and through additional field research to identify the most important areas of the Core Habitat.

Additional Information

If you have any questions about this report, or if you need help protecting land for biodiversity in your community, the Natural Heritage & Endangered Species Program staff looks forward to working with you.

Deerfield

Core Habitat BM454

This Core Habitat encompasses a stretch of the Connecticut River at the confluence of the Deerfield River. In addition to the river itself, the islands, shores, and rocky ledges provide habitat for Bald Eagles, a diversity of plant species, as well as several rare species of dragonflies, damselflies, and tiger beetles. While some portions of this Core Habitat are within the Connecticut River Greenway State Park, much of the habitat appears to be unprotected.

Natural Communities

This Core Habitat contains several islands in the Connecticut River that contain good-quality examples of High-Energy Riverbanks. High-Energy Riverbank communities are sparse, open graminoid communities found on cobble and sand deposits along fast-flowing rivers that experience severe flooding and ice scour.

Plants

This Core Habitat contains a diversity of rare plant species. Two rare members of the Aster family, Tradescant's Aster and the Upland White Aster, grow along the ledges and outcrops that line the Connecticut River. Other rivershore rare plants found here include the prostrate Sandbar Cherry, the Sandbar Willow, and an uncommon variety of Tufted Hairgrass.

Invertebrates

This Core Habitat includes a 5-km stretch of the Connecticut River between Greenfield, Deerfield, and Montague that is habitat for rare species of dragonflies, damselflies, and tiger beetles. Pollution or hydrologic alterations originating upstream, downstream, or within this Core Habitat are major threats to these insects.

Vertebrates

This Core Habitat encompasses partially forested islands and shorelines along over a mile of the Connecticut River in Montague and Greenfield. These provide relatively undisturbed perching and foraging habitat for wintering and non-breeding Bald Eagles.

Core Habitat BM490

Along the lower Deerfield River, this Core Habitat encompasses many riverine communities, including several large areas of Major-River Floodplain Forest. Here riverside and upland habitats support Wood Turtles and a diversity of rare plant species, such as the unusual Green Dragon.

Natural Communities

This Core Habitat contains the many sections of Major-River Floodplain Forest occurring along the Deerfield River. Major-River Floodplain Forests are dominated by Silver Maple. This community type is found along the floodplains of large rivers. The soils are enriched with nutrients brought by annual floods, resulting in a diversity of plants and insects. This Core Habitat includes a very large, high-quality example of a Major-River Floodplain Forest that is free of exotic species and human disturbances. The presence of several such communities near each other enhances the habitat value of each. Associated communities along this river include High-Energy Riverbank and Riverside Rock Outcrop community types.

Massachusetts Division of Fisheries and Wildlife

Deerfield

Plants

Several rare plant species adapted to riparian habitats are found growing within this long Core Habitat along the Deerfield River. For example, several populations of the Mountain Alder grow in open areas of rocky substrate along the river, while populations of Green Dragon are found areas of floodplain forest. One of only four Massachusetts populations of Spiked False Oats is found here within a Riverside Rock Outcrop Community.

Vertebrates

The meandering lower Deerfield River, with abundant islands and adjacent oxbow wetlands, fields, and upland forests, provides habitat for Wood Turtles. Most of the area is currently unprotected and conservation efforts aimed at preserving a viable population of Wood Turtles here should seek to protect unbroken riparian corridors that are at least 600 yards wide where possible.

Core Habitat BM522

This Core Habitat contains several different habitats, from the Connecticut River up to the Mount Toby State Forest. This long stretch of the Connecticut River and surrounding uplands provide valuable habitat for a number of rare dragonfly species, three of which are Endangered, as well as for Bald Eagles. Several rare plant species can be found in different sections of the Core Habitat. The land in and adjacent to Mount Toby State Forest supports significant populations of Eastern Box Turtles and Jefferson Salamanders, as well as other rare vertebrates, and provides key habitat for a variety of birds in an increasingly developed landscape. Mount Toby itself has an outstanding collection of natural communities, including some of the highest-quality rock cliff communities in the state. Parts of this Core Habitat are protected as conservation land, and further habitat protection would help ensure the long-term viability of the rare species found here.

Natural Communities

Mount Toby has many wonderful examples of Calcareous Rock Cliffs and Calcareous Talus Forests tucked into its large forested landscape. Calcareous Rock Cliffs are sparsely vegetated cliff communities. Unusual, highly specialized plants and ferns grow in rocks and ledges in the calcium-rich cliff face. This type of cliff community has more species diversity than Acidic Rock Cliffs. Calcareous Talus Forest communities develop on boulder strewn slopes below certain cliffs, with scattered trees, shrubs, vines, and ferns. There is often a gradient of vegetation density as the slope changes, with more trees on the lower slope. These two communities are typically very rich in species and often include many state-listed plants. As they are free of disturbances and exotic invasive plant species, Mount Toby has a collection of some of the highest-quality rock cliff communities in the state. There are also associated calcareous wetland types that are uncommon in the state, such as Calcareous Sloping Fen, Calcareous Seepage Marsh, and Black Ash-Red Maple-Tamarack Calcareous Seepage Swamp.

Plants

A wealth of plant diversity is present within this large Core Habitat, including one of the state's most viable populations of Autumn Coralroot, a small orchid.

Deerfield

Invertebrates

This Core Habitat includes a 13-km stretch of the Connecticut River and surrounding uplands in Deerfield, Whately, Montague, and Sunderland that are critical habitat for a host of rare dragonfly species, including the Spine-crowned Clubtail, Midland Clubtail, and Riverine Clubtail, all Endangered; the Threatened Arrow Clubtail; and the Cobra Clubtail and Skillet Clubtail, both Species of Special Concern. While some portions of the Connecticut River here are within the Connecticut River Greenway State Park, most of the habitat appears to be unprotected. Pollution or hydrologic alterations originating upstream, downstream, or within this Core Habitat are major threats.

Vertebrates

This Core Habitat includes an oval-shaped, largely roadless area that encompasses Mt. Toby State Forest and large areas of hilly, mixed forest to the south, nearly ten miles of small brooks and streams, small riparian wetlands, and scattered vernal pools. Significant populations of Eastern Box Turtles and Jefferson Salamanders occur here. Habitat for Wood and Spotted Turtles is present in Long Plain Brook and tributaries of Gunn Brook and associated wetlands. This area also provides a relatively large, unfragmented block of breeding and migration habitat for a variety of forest birds in an increasingly developed Connecticut River Valley. It is transected by two shrubby powerline corridors that provide habitat for Mourning Warblers and other birds of shrublands and forest edges. Much of this area is currently unprotected.

Also included in this Core Habitat are over eight miles of the Connecticut River, including both shorelines and several islands, that provide foraging and perching habitat for wintering and non-breeding Bald Eagles. This area extends from about one mile south of the Sunderland Bridge (Rte. 116) north to the railroad bridge that crosses the river in East Deerfield.

Core Habitat BM596

Invertebrates

This Core Habitat includes a 2-km stretch of the Mill River and associated uplands that are habitat for the Skillet Clubtail dragonfly. The surrounding landscape is forested and for the most part unfragmented, which protects the river from pollution. This Core Habitat is less than 7 km from other habitat for the Skillet Clubtail along the Connecticut River, which probably allows for dispersal of Skillet Clubtails between these two locations. This Core Habitat appears to be unprotected.

Deerfield

Core Habitat BM605

This Core Habitat, encompassing riparian habitats along the Mill River in Whately, Hatfield, and Deerfield, supports a variety of rare plants and animals. For example, the area is home to several rare species of dragonflies, including the Endangered Zebra Clubtail dragonfly. It provides significant habitat for Wood Turtles, and supports a large population of Green Dragon, an unusual rare plant. The Core Habitat also encompasses large and high-quality examples of two of the state's more unusual wetland communities. This Core Habitat is vulnerable to development, pollution, and hydrologic alterations.

Natural Communities

This Core Habitat contains the highest-quality Transition Floodplain Forest known in the state. Transitional Floodplain Forests are riverside Silver Maple-Green Ash-American Elm forests that experience annual floods. Of the three floodplain forest community types, these communities are intermediate in vegetation and soils. Most examples of this rare community type are severely affected by alterations in hydrology and are consequently overrun with non-native plant species. A large example of this community that is minimally affected by human disturbances and exotic plants occurs in Hatfield, where it is found within a large area of agricultural land. In Whately this Core Habitat contains a large example of the very uncommon Black Gum-Pin Oak-Swamp White Oak "Perched" Swamp. This community is an unusual type of wetland found in Massachusetts in one area of the Connecticut River Valley. This community type is dominated by Red Maple, with Black Gum, Pin Oak, and Swamp White Oak.

Plants

A large population of the unusual Green Dragon, a relative of Jack-in-the-Pulpit, is found in a floodplain forest within this riparian corridor.

Invertebrates

This Core Habitat includes a 17-km stretch of the Mill River in Whately and Hatfield that is important habitat for both the Zebra Clubtail dragonfly and the Brook Snaketail dragonfly. Also along the Mill River within this Core Habitat, in the northern part of Whately, is an area of wetlands and meadows with thickets of Elderberry that are habitat for the Elderberry Longhorned Beetle. This Core Habitat is located less than 10 km from Core Habitat in Williamsburg (habitat for the Elderberry Longhorned Beetle) and from Core Habitats in Hadley and Northampton (habitat for the Zebra Clubtail and Brook Snaketail dragonflies), which potentially allows for dispersal of these rare insect species between these various habitats.

Vertebrates

This long meandering stream with sandbars and bordering wooded swamps, wet meadows, upland forests, and fields provides significant and connected habitat for Wood Turtles. To benefit Wood Turtles, conservation efforts should seek to preserve unbroken corridors up to 600 yards wide all along the Mill River. Within this Core Habitat, forested and shrub wetlands and riparian forests also provide valuable spring migration habitat for a variety of songbirds.

Deerfield

Core Habitat BM617

Natural Communities

This Core Habitat contains a Black Gum-Pin Oak-Swamp White Oak "Perched" Swamp. These swamps are an unusual type of wetland found in Massachusetts in one area of the Connecticut River Valley. This community type is dominated by Red Maple, with Black Gum, Pin Oak, and Swamp White Oak. Here the large swamp is partially buffered by naturally forested upland.

Core Habitat BM636

Natural Communities

This Core Habitat includes a Circumneutral Rock Cliff community. This type of community consists of extremely sparse plants growing on small ledges and in crevices on a circumneutral cliff face. These communities tend to support a greater diversity of species than Acidic Rock Cliff communities. Here the rock cliff is made of a rare type of sandstone and supports a unique assemblage of plant species, including many species that are state-listed.

Living Waters: Core Habitat Summaries

Deerfield

Core Habitat LW256

This cobble-bottomed section of the Deerfield River supports a population of Threadfoot, a Threatened plant species in Massachusetts. Threadfoot is one of the few freshwater plant species adapted to live in swiftly flowing waters. It uses fleshy pads to anchor itself to cobbles and rock ledges. Although able to withstand seemingly harsh natural conditions, this species is susceptible to siltation, water pollution, and drastic changes in water flow.

Core Habitat LW354

This middle section of the Connecticut River flows through a mix of developed, agricultural, and forested lands, and is bounded by the Holyoke dam to the south, and the Tuners Falls dam to the north. The river provides unparalleled freshwater habitats for fishes and invertebrates in Massachusetts.

The river is of conservation significance because it supports the only known occurrence of the Endangered Yellow Lampmussel in Massachusetts. This freshwater mussel lives in large rivers, and was recently rediscovered in the mainstem of the Connecticut River at depths of up to fifteen feet. In the past, the Connecticut River was known to support eleven mussel species, and today there are nine species known from the river.

The Bachelor Brook tributary in Granby and South Hadley also supports a very diverse assemblage of freshwater mussels, including eight of the twelve species found in Massachusetts. Four of these species are state-listed as rare: the Endangered Brook Floater, the Triangle Floater, the Eastern Pondmussel, and the Creeper mussel. These species have generally been found in moderate to slow flowing stretches of the brook below rocky riffles in either mixed sand and gravel runs or in sandy pools. The Brook Floater in particular is believed to be sensitive to low oxygen, pollution, and silt, and is known from only five water bodies in the state. There is some evidence that this small Brook Floater population is reproducing, making this a particularly important site.

Stony Brook in South Hadley supports five freshwater mussel species, including the rare Creeper mussel. This species is found scattered along the lower reach of Stony Brook, near the confluence with the Connecticut River, as it flows slowly over loose sands, gravels, and clays. There are only nineteen Core Habitats for the Creeper, which represent the water bodies that support the most robust populations of this rare mussel across the state.

From Holyoke northward, the Connecticut River mainstem is also home to ten species of state-listed dragonflies, the majority of which are found only in large rivers. The tributaries of the Connecticut River are important habitat for the state-listed dragonflies found in smaller rivers. The Connecticut River and the Connecticut River Valley provide a northward corridor for more southerly species, thus contributing a unique fauna to Massachusetts.

In addition to invertebrate habitats, the Connecticut River supports a diversity of fish habitats. The stretch of the Connecticut River in Montague is an important spawning (breeding) area for the state- and federally-Endangered Shortnose Sturgeon. This long-lived, prehistoric-looking fish is particularly susceptible to habitat degradation and mortality because it does not reach

Living Waters: Core Habitat Summaries

Deerfield

maturity until it is at least 5 - 10 years old. The Shortnose Sturgeon moves many miles during its life cycle, using other parts of the Connecticut River at different times of the year. The stretch of the river from Montague and Deerfield down to Hatfield and Hadley is important feeding and overwintering habitat.

In Hatfield, Hadley, and Northampton, a portion of the Connecticut River and its associated tributaries were delineated as Core Habitat for the Eastern Silvery Minnow, a fish Species of Special Concern. This species is only known from the Connecticut River and lower Deerfield River in Massachusetts. It spawns in backwaters, laying eggs directly on the river bottom in areas where the emergent vegetation provides cover. Siltation, pollution, and water level changes threaten this species.

The stretch of the Connecticut River in Gill, Greenfield, and Montague downstream from the Turners Falls Dam is presumed habitat for Burbot, a fish Species of Special Concern. Burbot also likely inhabits the Connecticut River in the vicinity of the Fort River confluence in Hadley. This enigmatic fish, a freshwater member of the cod family, has been found at only a few locations in Massachusetts. Not much is known about its life history in the state, although it may live mostly in deep pools of the Connecticut River.

Shallow areas in the Connecticut River north of the Sunderland bridge support a population of the diminutive American Waterwort, an Endangered aquatic plant. This area also supports the uncommon Water Star-Grass, a plant with tiny yellow flowers and long grass-like leaves. Native freshwater plants like these species are an important component of aquatic ecosystems. They provide habitat and nutrition for fish and invertebrates, and they add oxygen to the water through photosynthesis. Permanent protection of the riparian land adjacent to this Core Habitat, and careful management of runoff from developed and agricultural areas will help ensure the continued quality of this key Core Habitat in Massachusetts.

Core Habitat LW362

The lower reaches of the Deerfield River provide habitat for the state- and federally-Endangered Shortnose Sturgeon. This long-lived, prehistoric-looking fish uses the area as a refuge from high springtime flows in the Connecticut River mainstem. This species is particularly susceptible to habitat degradation and mortality because it does not reach maturity until it is at least 5 - 10 years old. The Shortnose Sturgeon moves many miles during its life cycle, using different parts of the Connecticut River for breeding, feeding, and overwintering.

Core Habitat LW425

The Mill River in Whately and Hatfield is considered to be the top conservation priority for freshwater mussels in Massachusetts. The river supports the most diverse assemblage of mussels known in the state, including a viable population of the state- and federally-Endangered Dwarf Wedgemussel. Also among the nine mussel species found here, are the rare Triangle Floater, the Eastern Pondmussel, and the Creeper mussel. The river habitat is unique because below the falls near route 116 in Deerfield, the gradient of the Mill River flattens and the river slowly flows across the old lakebed of former Glacial Lake Hitchcock. Here the riverbed is made up of softer sands, silts, and clays, which allow mussels to successfully get a foothold in the bottom sediments. Robust populations of many of these

Deerfield

mussel species, along with clear evidence of reproduction, further attest to the importance of this site for freshwater mussel biodiversity.

Tributaries to the Mill River, Running Gutter and Broad Brooks also support diverse communities of freshwater mussels, including the state- and federally-Endangered Dwarf Wedgemussel, and the uncommon Eastern Pearlshell mussel. Both of these species are found in the low gradient stretches of Running Gutter Brook in patches of sand and silt. The beaver dams in this brook likely benefit mussels. Beaver dams slow water flow and trap sediments, which allow mussels to get a foothold in an otherwise quick flowing environment.

This Core Habitat also supports rare dragonflies. These aquatic insects are good indicators of ecosystem health, confirming that this Core Habitat contains high-quality freshwater habitats for aquatic species.
